

Validation

Data Annotations

- Enable automatic validation by decorating model properties with data annotation attributes such as `[Required]`
- Heads up: data annotations on entities also work but have a different database related meaning
- When `[ApiController]` is used, handling validation errors is automatic
- Validation status can also be accessed using `ModelState`
- For minimal APIs data validation is manual (there are NuGet packages to help with that)

Problems

- A Problem is a standardized error response from an API
- It works by default through built-in middleware
- Behaviour can be changed by extra configuration
